

Relay protection setting drift

Overview

In reality, protection relays drift out of calibration over time due to multiple factors: aging electronics, environmental stress, secondary circuit issues, firmware/software changes, and operational conditions. Drift is progressive and can lead to false trips, delayed fault clearance, protection. The selected protection principle affects the operating speed of the protection, which has a significant impact on the harm caused by short circuits. Further, the duration of the voltage. Protection relays employ a wide range of configurable parameters to identify defects & trip the breaker in a controlled & selected manner. Understanding each setting facilitates proper relay coordination. Direction: Forward Typically required zone 2 reach impedances = 100% line impedances of the protected section + 50% impedance of adjacent shortest line. The zone2 time delay. With this Protection Relay Setting Calculator, you'll be able to work out pickup current, time multiplier settings (TMS), operating time, coordination time interval (CTI), and plug setting multiplier (PSM) based on fault current, CT ratio, and the IEC 60255 curve parameters.
